PREFACE

- The National Radiation Protection Institute (NRPI) is a non-profit organization established by the decision of the chairman of the State Office for Nuclear Safety (SONS) on May 26, 1995, which became effective on July 1, 1995. The Institute was based mainly on the former Centre for Radiation Hygiene of the National Institute of Public Health in Prague transferred under the authority of SONS, and it continues its tradition of many years.

- Institute research is focused on protection against ionizing radiation, including the provision of infrastructure and research in areas of:
  - Security research
  - Radiation Monitoring Network research
  - Research on exposures to artificial sources of ionizing radiation
  - Research on medical exposures
  - Research on exposures to natural radiation sources.
PREFACE

The NRPI - Department of Natural Exposure – Radon/Thoron Lab.
- organizing inter-comparisons (since 2010)
- participates in R&D Projects
- participate in a special radon diagnostics in a house under the scope of a National radon action plane

MAIN GOAL

- Financial benefit

TARGET QUANTITIES OF INTEREST

- Radon / thoron gas concentration in air including their mix field
- Short- lived radon/thoron decay products in air (EEC)
- Unattached and attached part of EEC
  (focused on all the types of measuring instruments i.e. spot, passive integral, and continuous monitors):
- Air exchange rate in buildings (continuously, passive integrals).
# THE NRPI - CERTIFICATE OF ACCREDITATION

## Accredited entity according to ČSN EN ISO/IEC 17025:2005:

- **Státní ústav radiční ochrany, v.v.i.**
- **SURO Testing Laboratories**
- **Bartolíkova 1450/28, 140 00 Praha 4**

THE NRPI METROLOGICAL (QA) CONCEPT

I. Is based on existence:

A) Relevant measurement standard for each mentioned quantity of interest.

B) Used comparing instrument for each quantity of interest allowing transfer of relevant quantity from the standard to another instruments and an independent control of self metrology in renowned Labs.

C) Two crucial tools allowing both routine calibrations and applied research (The NRPI is a scientific institution - not pure metrological):
   i.e. a big radon chamber and a small thoron/radon chamber.

II. Is focused primarily on:
   Indoor ambient conditions i.e. p, T, RH, aerosol concentration and size distribution, air exchange rate, surface of walls etc. (available in the big chamber).

Measured ASD with SMPS + C (Grimm)
Single Nano Particle Counters Series 5.400

SMPS+C = CPC + DMA + Software

By adding a DMA the user can upgrade the CPC to a high resolution Scanning Mobility Particle Sizer (SMPS+C) that records size distributions between 5 and 1100 nm.
Outdoor aerosol size distribution and indoor activity size distribution

Fig. 8. Aerosol size distribution measured with SMPS (a) in the MBL below 800 m and (b) above cloud layer.
An alternative methods used for assessment of fp

- Approximations according to Prof. Pörstendorfer (J- P. room model) via measured ratio of unattached (F)/attached(A) activity of $^{218}$Po as follows:

$$X = \lambda_1 \left( a_1^{iF} / a_1^{iA} \right) - (\lambda_1 + ACH + q^A)$$

$$q^F = \lambda_1 \left\{ \left[ a_0^{i} / (a_1^{iA} + a_1^{iF}) \right]^{-1} \right\} - (\lambda_1 + ACH + X)$$

- Calculation of the attachment rate $X$ by means of measured aerosol size distribution $Z(d)$ and known attachment coefficient $\beta(d)$ as follows:

$$X(Z) = \int_0^\infty \beta(d)Z(d)dd$$

- Algebraic inversion of the J- P. room model (Dr. J. Thomas)

- Calculation of ACH via the tracer gas method.
Comparing instrument Fritra 4 for $^{222}\text{Rn}/^{220}\text{Rn}$ progeny including their unattached and attached fractions

Fig.16  An example of measured radon outdoor daily variations and used radon low-level measurement instruments
The purpose of a (QA/QC) program is:
to ensure proper processes are followed by all individuals responsible for radon measurements so that if errors do arise they will be recognized early on. The source of the error should be identified, and adjustments shall be made to correct issues to ensure that high quality results are obtained.

Quality Control — the process of measuring the ongoing performance of its devices to ensure continued conformance to established performance standards;

USEFUL DEFINITIONS:
Accuracy - refers to the closeness of a measured value to a standard or known value.
Precision — refers to the closeness of two or more measurement results to each other.
Calibration - correcting a measuring instrument by measuring values whose true values are known

Lowest Level of Detection (LLD) LLD is based on the detector and analysis system's background and can restrict the ability of some measurement systems to measure low concentrations.

Quality Assurance Plan — the planned and systematic activities implemented in a quality system to ensure that quality requirements are met.
Quality Control — the process of measuring the ongoing performance of its devices to ensure continued conformance to established performance standards;

Relative percent differences (RPD) — comparison of two measured values

Relative Percentage Error (RPE) — a measurement of inaccuracy

Reference value (RV) — conventionally true value

Uncertainty - is the total error generated by precision and accuracy errors.

Quality Assurance Plan must include the following elements:

I. Background information on the organization
II. Name of Organization’s Radon QA/QC Coordinator
III. Organization’s Radon Services Offered
IV. Identify Radon Devices Used
V. Identify Employees Using Radon Measurement Devices and Personnel Qualifications
VI. Work Flow Control and Radon Test Procedures (measurement Protocols)
VII. Documentation and Record Control
VIII. Change Control (measures that need to be taken after an error is discovered)
IX. Calibration and Maintenance Plans
X. Procedures for Non-Conformances and Corrective Action

Within QC process we should focus on following five procedures:
1. **Calibration**

Measurement device calibration is to be conducted in accordance with the manufacturer’s recommended calibration schedule. The calibration is to be conducted by the manufacturer or an authorized representative of the manufacturer. Calibration ensures that the machine is operating properly and measuring accurately.

2. **Spike/Performance tests or inter-comparisons (blind proficiency test)**

are to be conducted according to recommended schedule. Blind performance testing or inter-comparisons involve sending the radon devices to the organizer of the inter-comparison, where the radon devices will be placed in an accredited radon chamber and exposed to a known radon concentration.

- To calculate the acceptance range you need to use the calculation to determine the Relative Percentage Error (RPE).

\[
RPE = \frac{(MV-RV)}{RV} \times 100\%
\]

*where:*

RPE = relative percentage error;
MV = measured value of spiked measurement; and
RV = reference value.

Tests are acceptable if: (they are within +/- 25% at radon levels of 150 Bq/m3 or greater)
3. **Field duplicate tests (or Duplicates)** are quality control measurements designed to assess the precision of radon measurement devices. Duplicate tests are required for every 10% of tests deployed by an organization. The first detector deployed by the measurement provider should be a duplicate and every 10th test after that should also be a duplicate test.

- Duplicate tests should be conducted by placing two radon devices side-by-side, 10 cm (4”) apart. The test duration for the two devices must be the identical, meaning that the start and stop must be the same.

- Duplicates provide assurance to an organization that the tests are providing acceptable precision. Duplicate measurements should be compared by calculating their relative percent difference (RPD)

- Calculating Relative percent differences: \(|\text{Test 1} - \text{Test 2}| / ((\text{Test 1} + \text{Test 2})/2) \times 100\)

The following chart provides guidance on allowable variances in RPD for duplicate tests.

<table>
<thead>
<tr>
<th>Average Test Measurement</th>
<th>Acceptable RPD</th>
<th>Warning Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;75 Bq/m³</td>
<td>No limits</td>
<td>No limits</td>
</tr>
<tr>
<td>75 – 149 Bq/m³</td>
<td>Less than +/- 25%</td>
<td>+/- 25 to 50%</td>
</tr>
<tr>
<td>Over 150 Bq/m³</td>
<td>Less than +/- 14%</td>
<td>+/- 14 to 28%</td>
</tr>
</tbody>
</table>

Duplicate measurements should be recorded and tracked on a spreadsheet by the organization and analyzed for changes or trends via control charts.

If Duplicate measurements fall outside the Acceptable RPD than action should be taken to determine why the error occurred and how many past tests may have been affected.
4. **Cross-checks** are similar to duplicate tests however the device used needs to be **approved** device. In a situation where a professional is using a continuous radon monitor a cross check should be done every six months to identify any anomalies with the testing equipment in between calibrations.

If a standard check source is available for the device, it can be used for the cross-check purpose. i.e (such as an in-built one)

A cross-check should be conducted for at least a 48 h period and can be conducted using a second device setup up side by side (within 10 cm or 20 cm apart).

The devices should be with in allowable limits as specified in the previous section 3. **Duplicates.**
5. **Blank tests** are designed to measure the limit of detection of the radon measurement device by assessing any background exposure which may increase the lowest limit of detection from the manufacturers stated levels.

- The detection limit is defined to be the lowest concentration of radon that can be measured with a certain confidence. The detection limit is calculated by the manufacturer of measurement devices but then it could be elevated by background exposure which interferes with the actual radon test.
- Blank tests are required for every 5% of tests deployed by an organization. The second test deployed by the organization should be a blank and every 20th test after that should also be a blank test.
- The lowest level of detection must be supplied to the measurement provider by the lab as this is a value calculated on each batch.
- There a multiple types of blank tests depending on the device type.
- **Lab Blanks** – these are blanks that are sent away by the lab after manufacturing to assess any background exposure that a device has while waiting to be deployed by a measurement professional. A lab must retain 5% of its devices to expose at least one device each time a batch is sent to a purchaser.
- **Transit Blanks** – these are blanks that are sent back to the lab by the measurement professional to ensure that there was no contamination to the shipment of radon tests during transit from the lab to the measurement professional.
- **Field Blanks** – these are blanks that are sent to the lab as blind tests to verify that the devices are not being exposed to background exposure which would interfere with regular radon tests.

Field Blanks should be conducted by following the same procedure as used for duplicates – however the blank detector or device will not be opened or activated until the end of the test, where it would be opened and sent to the lab to be treated the same as one of the exposed devices when analyzed by the lab.

*Blank tests are acceptable if they are within +/-10% the devices lowest level of detection as determined by the manufacturer.*

NOTE 2
LEGALLY CONTROLLED MEASURING INSTRUMENTS

Legally controlled measuring instrument have to conforms to prescribed legal metrological requirements.

We distinguish between a two basic metrological acts with respect to measurement instruments:
   a) calibration (provided by a private Accredited Labs)
   b) verification (provided by an State Authorized Labs)

The goal:
To prevent customers against consequences of incorrect measurements made in the field of official transactions, working conditions, public health and work safety a Decree of Ministry of Industry and Trade sets list of instruments for mandatory verification.

The Decree is attached to the Czech version — see on Czech version.
CONCLUSIONS

The NRPI facility allows calibration for all the types of measurement instruments i.e. spot, passive detectors and for continuous monitors in a mix field of $^{222}\text{Rn}/^{220}\text{Rn}$.

The NRPI calibration way based on measurements standards eliminate a potential problems with „a reference“ instruments as the AlphGUARD, RAD 7 etc.

The NRPI radon gas metrology is based on the Czech 226 Ra standards produced by the Czech Metrological Institute and thoron metrology on PTB 228 Th.

Attention is also payed to radon/thoron decay products in their mix fields QA/QC system for radon/thoron gas and radon its short-lived decay products including fp measurement instruments developed at the NRPI and cross-checked both within the intercomparisons and solo in the renowned Labs.

as the PTB (D), BfS (D), AMC Kamenna (CZ) declares overall calibration uncertainties as follows:
- less than 5% (K=1) for radon gas
- less than 10% (K=1) for thoron gas
- less than 10% (K=1) for short-lived decay products
- less than 20% (K=1) for $f_p$.
